

AD1 : A generic workflow execution showing the progression of a workflow instance from creation or start until completion or another appropriate final outcome.

This is what TIVIDY does for *any* workflow. A start request comes in, the engine checks the definition, and creates a fresh instance from it. Then it loops: make work available, assign it, do it, record it, and check what can start next. The fork shows independent work running in parallel, and the called activity is a sub-process. When no work is left, the instance ends as completed, cancelled or failed

AD2: Another important generic TIVIDY workflow, such as work assignment and completion, approval and escalation, failure and recovery.. This zooms into one engine behaviour: what happens when an approver doesn't respond. The definition supplies the approval chain and the deadline. If the approver answers in time, we get an approval or rejection. If not, the engine escalates to the senior approver, and if they also miss it, to a final fallback. Every route ends at the engine, which records the outcome and updates the work item. The approver is the Hiring Manager in our scenario, but the diagram itself stays generic.

AD3: An important workflow from your selected scenario

Here is TIVIDY running our onboarding. The lanes show who does what. New hires submit documents in a loop until HR is satisfied, then the Hiring Manager approves. Verification is a called activity, and if it fails we cancel and roll back. If it passes, a fork runs the setup tasks (profile, payroll, uniform and card, email) in parallel, and the join waits for all of them before induction. The Hiring Manager confirms and HR marks the employee onboarded.
